REGIONAL FLOOD FREQUENCY ANALYSIS FOR SMALL NEW ZEALAND BASINS 1. MEAN ANNUAL FLOOD ESTIMATION

A I McKerchar

formerly: Hydrology Centre, P O Box 22037, Christchurch now; NIWAR Freshwater, Box 8602, Christchurch.

ABSTRACT

One hundred and forty New Zealand basins with areas of less than 100 square kilometres were used to investigate regional methods for estimating mean annual floods for small ungauged basins. Besides the usual sample estimate of mean annual flood, data on slope, soil and hydrogeology were processed from the New Zealand Land Resources Inventory for each basin. Other variables used in the prediction of mean annual flood were basin area, and three rainfall statistics for each basin: 1-hour and 24-hour 5-year return period intensities, and mean annual totals. Multiplicative regression models using catchment characteristics were less precise than McKerchar and Pearson specific mean annual flood contour maps.

INTRODUCTION

Regional flood frequency analysis using the flood index method has two parts: estimation of mean annual flood (index flood) and estimation of dimensionless flood frequency growth curves. This paper addresses mean annual flood estimation for small New Zealand basins and Pearson (this volume) addresses dimensionless flood frequency.

Estimation of mean annual flood for basins where there are no records continues to be a weakness of regional flood frequency methods, despite efforts to improve estimators.

Beable and McKerchar (1982) developed a set of regression equations of the form

$$Q_m = a A^b P^c I^d$$
,

where: Qm is mean annual flood

A is basin area

P is mean basin rainfall

I is 24-hr rainfall intensity with a 2-yr return period

a,b,c and d are constants

Each equation was applicable for a "region" where regions were defined in terms of geographical differences, but adjusted to fit groups of adjacent basins where estimation errors for an overall equation were consistently either negative or positive. Factorial standard error of estimate for these equations was in the range 1.21 to 1.47, and equivalent to errors where Q_m is estimated from one

to five years of record. These error statistics are likely to be underestimates because they do not include uncertainty about the placement of regions.

Mosley (1979) used morphologic reach and cross-section variables to estimate Q_m for 73 South Island rivers. The factorial standard error for the best equation using all 73 rivers was 1.71. This reduced to 1.52 for 63 non-braided rivers.

McKerchar and Pearson (1989) drew contour maps to use to estimate $Q_m/A^{0.8}$ (division by $A^{0.8}$ removes the effect of basin area) for any basin. The maps were developed using data from 343 basins. Proportional errors of estimates from the maps were defined by:

$$E = 100 (Q_{mr} - Q_{ms})/Q_{ms}$$

where: Q_{mr} is the "regional" mean annual flood estimate inferred from the map, and Q_{ms} is the "at-site" estimate of mean annual flood, i.e. the estimate of Q_m from the flood series.

E values showed a mean of 8.6%, (i.e. the bias) and a root mean square error of $\pm 55\%$

E values ranged from -69% to 578%. Nineteen sites, (i.e. 5% of sites) with E exceeding 70% were discarded as outliers. Statistics for the remaining 95% of sites were bias = -0.9% and root mean square error = $\pm 22\%$, so that the standard error of estimate of Q_m from the maps was $\pm 22\%$. This was an improvement over the Beable and McKerchar equations, which also discarded about 5% of the catchments as outliers.

Results were more variable for small basins than for larger basins. For all basins with areas less than 10 km², McKerchar and Pearson obtained the following:

| | No. Basins | Bias (%) | Root Mean Square Error |
|--------------------------------|------------|----------|---------------------------|
| All basins <10 km ² | 49 | 22 | 92 |
| Outliers excluded | 43 | -0.7 | 34 |

Outline of problem

The error statistics for "all basins <10 km²" are unacceptably large for design flood estimation. With "outliers excluded" the error statistics are acceptable, but the question of what is an outlier is not resolved, and this raises doubt about the reliability of the method. Also, the outliers are disproportionately represented among the basins with area <10 km². Are the six records all in error, or are they conveying information about hydrological conditions not adequately represented by the contour maps? For example, the scale of the maps and the level of smoothing in their contours may mask much real variation between small basins. Can additional information be employed to improve regional estimates of flood statistics?

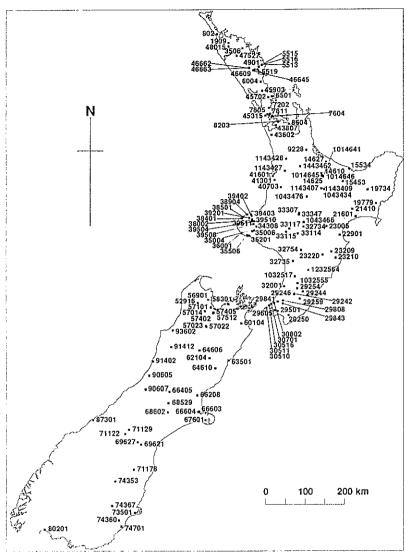

FIG. !—Location of the 140 small (A ≤ 100 km²) New Zealand basins used in this study. Site numbers from Walter (1990).

The additional information available in the NZ Land Resource Inventory (Ministry of Works and Development, 1979) includes broad classes of rock type, overland slope, vegetation and soils. This information can be extracted from a database for any basin boundary, and this study sought to use it to improve estimates of mean annual flood for small basins.

METHOD

Data compilation

To assemble sufficient data for comprehensive analysis the area threshold was raised from 10 to 100 km². Data for 140 basins with areas less than 100 km², and at least six years of flow records were assembled (Fig. 1).

The data assembled for each basin were:

- Mean annual flood (Q_m) : This quantity is the arithmetic mean of peak discharges for each of at least six years of record. These data were extracted from streamflow archives up to and including 1989 (Tideda: Rodgers and Thompson, 1991). Length of record (N years) is given beside the mean. Where possible the stage series are checked for consistency against records for adjacent basins. Reliability of the rating curves, which are calibration curves to transform stage to discharge, is problematical. Most of these small basins are fitted with weirs or bed-control structures calibrated using laboratory data. Where field calibration is limited to low flows, it is difficult to determine whether the adopted ratings are correct, especially at flood extremes beyond the range of conventional laboratory calibrations. This implies that annual maximum flood peak estimates for these basins are less reliable than those for basins with higher-stage current-meter gaugings (Potter and Walker, 1985).
- Area (A): Basin area is defined on the NZMS 260 (1:50000) or NZMS I (1:63360) map series, and listed in Walter (1990).
- Rainfall intensity (I₁ and I₂₄): Five-year return period rainfall depths for 1-hr and 24-hr duration storms were estimated from maps in Tomlinson (1980). These depths are areal means for each basin, but are not adjusted by areal reduction factors. In the Tomlinson maps I₁ is estimated from a sparse network of recording raingauges, whereas I₂₄ is estimated using a much more comprehensive set of daily-read manual raingauges, and is more reliable.
- Mean annual rainfall (P): An areal mean annual rainfall was estimated from the map of 1951-1980 normals in NZ Met. Serv. (1985).
- Hydrogeology (H): Derivation of a basin estimate of "hydrogeology" is explained in Hutchinson (1990). In summary, each combination of rock types in the Land Resource Inventory is assigned a scalar number ranging from 1 for low to 8 for high bedrock infiltration capacity and transmissibility. Low values are assigned to strongly indurated sedimentary rocks, and igneous and metamorphic rocks. Medium values are assigned to pyroclastics, loess, crushed argillites, "soft" volcanics, and weakly indurated sediments. High values are assigned to ashes, breccia, scoria, lapilli, alluvium, colluvium, glacial till, peat and wind-blown sand. A basin mean is calculated as a sum weighted by the proportion of basin area occupied by each class.
- Slope (S): The Land Resource Inventory classifies parcels of land into seven slope classes A...G defined as:

A - 0-3°, flat to gently undulating

 $B - 4-7^{\circ}$, undulating

 $C = 8-15^{\circ}$, rolling

D — 16-20°, strongly rolling

E - 21-25°, moderately steep

 $F - 26-35^{\circ}$, steep

G ->35°, very steep

Areally weighted mean slope is calculated as:

$$S = 1.5 S_a + 5.5 S_b + 11.5 S_c + 18 S_d + 23 S_c + 30.5 S_f + 38 S_g$$

where S_a , S_b , ... S_g are the decimal proportions of the catchment area occupied by ground in the slope classes A, B, ... G respectively.

— Soil Properties: A soil description applies to each Land Resource Inventory parcel. Three soil properties considered to affect rapid runoff were (MJ Duncan, pers. comm., 1991):

— Soil drainage (D): a scalar ranging from 1 to 7, 1 representing very poor drainage, 5 representing well drained, 7 representing excessive drainage.

— Depth-weighted macroporosity (DWP): Macroporosity determined in the laboratory from field samples applies to a particular soil horizon. A depth-weighted value was calculated as an index of macroporosity for the whole horizon. Typically macroporosities are in the range 0 to 30%.

- Minimum porosity (MP): Minimum porosity for each soil class was

Area-weighted estimates of these three quantities were calculated.

All the data are assembled in the Appendix, and summary statistics are given in Table I.

TABLE 1—Summary of basin characteristic statistics of 140 basins listed in Appendix.

| CHARACTERISTIC | Q_{m} | Α | I_i | I_{24} | P |
|----------------|-----------|-------|-------|----------|-------|
| | (m^3/s) | (ha) | (mm) | (mm) | (mm) |
| MINIMUM | 0.054 | 1.420 | 13 | 45 | 550 |
| MAXIMUM | 389.2 | 9963 | 128 | 660 | 11700 |
| MEAN | 49.3 | 3061 | 34 | 154 | 1968 |
| STANDARD DEV | 69.1 | 2891 | 13 | 72 | 1301 |
| CHARACTERISTIC | Н | S | D | DWP | MP |
| | | (deg) | | (%) | (%) |
| MINIMUM | 1.0 | 1.5 | 1.0 | 1.2 | 0.0 |
| MAXIMUM | 8.0 | 35.4 | 7.0 | 29.3 | 26.0 |
| MEAN | 4.4 | 19.7 | 4.3 | 13.9 | 8.7 |
| STANDARD DEV | 2.5 | 8.0 | 1.1 | 6.1 | 5.0 |

Analysis proposed

Multiple regression is proposed for the analysis using the form

$$O_m = a X_1^b X_2^c ...$$

where: X_1 , X_2 ... are basin characteristics (e.g. Area A, mean annual rainfall P, hydrogeology H, etc), and a, b, c ... are coefficients determined by multiplicative regression.

Analysis with subsets of the data is proposed, with the subsets defined as:
a) arbitrary splits of the data, e.g. into four sets with high rainfall P and high minimum porosity MP, high P and low MP, low P and high MP, low P and low MP; with the high/low splits for P and MP taken as the median value.
b) Clusters of data using the algorithm K-means of SYSTAT (Wilkinson, 1986), which splits data into groups such that between-group variation is maximised and within-group variation minimised. Variation is measured as the Euclidean distance between data for a basin and the group mean. These methods avoid splits based on loose geographic regions.

RESULTS

Data statistics

The compiled data statistics (Table 1) reflect the very large range of hydrological conditions encountered across the country.

For example, mean annual rainfalls range from 550 to 11700 mm/yr, mean basin slopes from 1.5 to 35 degrees, depth-weighted macroporosity ranges from 1.2% to 29.3%, and minimum porosity ranges from 0% to 26.6%.

Hydrogeology and drainage, both measures of infiltration, are near their upper bounds for volcanic ash-covered Central North Island basins where $Q_m/A^{0.8}$ are low. For example for Mangakara (site number 1043434), hydrogeology H = 7.5, soil drainage D = 6.2, and the porosity measures (DWP = 26.1%, MP = 16.8%) are amongst the highest for all the 140 basins, and $Q_m/A^{0.8}$ is 0.36 (Q_m in m³/s, A in km²). In contrast, for two basins in Northland (Pukewaenga, 46662 and Pukeiti, 46663) intensity I_{24} = 155 mm is almost identical to Mangakara (I_{24} = 150 mm), but $Q_m/A^{0.8}$ = 5.0 and 5.4 respectively, and for both basins hydrogeology H = 4.0, soil drainage D = 1.0, depth-weighted macroporosity DWP = 2.1% and minimum porosity MP = 0.1%. The low values of the latter three parameters reflect the poor drainage and low porosities of the heavy clayey soils in these basins.

Another basin with unusually low values for $Q_m/A^{0.8}$ is Maryburn (71122) in the central South Island. Here $Q_m/A^{0.8} = 0.17$, and the intensity estimate is $I_{24} = 80$ mm. Hydrogeology H = 8.0, soil drainage D = 5.0, depth weighted macroporosity DWP = 20.1% and minimum porosity MP = 15.5%, are all greater than the respective means across all basins (Table 1). This basin has been discarded as an outlier in previous studies.

For many basins at the extremes of the dataset, there is an inverse correlation between the flood parameter $Q_m/A^{0.8}$, and the Land Resource Inventory — derived quantities, soil drainage D, depth-weighted macroporosity DWP and minimum porosity MP. This study seeks to verify this correlation across a large sample of data, and to use it to provide better estimates of Q_m for ungauged basins.

Correlations

For logarithms (base 10) of data, correlation coefficients (Table 2) are generally positive. Correlation of $\log{(Q_m)}$ with area is notable, but otherwise its correlations are weak. Correlations between the three rainfall parameters and between the three soil parameters are also notable. These suggest that just one rainfall and one soil parameter may be sufficient as independent variables.

TABLE 2—Correlation matrix for logarithms of basin characteristics.

| | Qm | Α | P | I_1 | I ₂₄ | Н | S | D | DWP | MP |
|----------|--------|--------|-------|--------|-----------------|--------|-------|-------|-------|-------|

Regression analysis

Table 3 gives a selection of regression results using all the data. The results given are the best result, in terms of minimum standard error, for 1, 2, 3, and 4 variables. The standard errors and factorial standard errors, of similar magnitude to those reported for country-wide equations in Beable and McKerchar (1982), are too large for the results to be used for design flood estimation.

TABLE 3—Multiplication regression results for prediction of Q_m using all 140 basins. "t" is Student's statistic; "R²" is coefficient of determination; and "s.e." is standard error.

| No. Variables | Variable Name | Coef. b,c,d | s.e. of coef | t | R | R² | s.e. | Factorial s.e. | Const log a | Multiplier a |
|------------------|----------------------------------|------------------------------------|-------------------------|------------------------------|-------|-------|-------|----------------|----------------|-----------------------|
| 1 | Α | 0.856 | 0.040 | 21.7 | 0.879 | 0.773 | 0.411 | 2.57 | 0.279 | 1.90 |
| 2 | A I ₂₄ | | 0.031 0.160 | 26.2 9.7 | 0.930 | 0.866 | 0.317 | 2.07 | -3.029 | 9.35×10 ⁻⁴ |
| 3 | A I ₂₄ H | | 0.028 0.146 0.077 | 28.7 11.2 -5.5 | 0.944 | 0.890 | 0.288 | 1.94 | -2.961 | 10.9×10 ⁻⁴ |
| 4 | A I ₂₄ H DWP | 0.848 1.679 -0.397 -0.606 | | 32.5 12.9 -5.8 -6.0 | 0.956 | 0.913 | 0.257 | 1.81 | -2.449 | 35.6×10 ₋₄ |

The data set was partitioned in a number of ways, including splitting the data into one of four groups depending on whether mean rainfall P and minimum porosity MP were above or below their median values. The most promising was to split between "high infiltration" and "low filtration" with low infiltration basins arbitrarily defined as having hydrogeology H < 7 and soil porosity DWP

< 11%. Standard error for 44 "low infiltration" basins was ± 0.184 , but this error is still too large for the results to be of practical use (factorial standard error of 1.53).

Other analyses

Other analyses, including cluster analysis, and use of an "infiltration" parameter, a sum of standardised values of D, DWP and MP, did not improve predictive capability.

DISCUSSION

This study was founded on the notion that the basin data from the Land Resource Inventory would provide a country-wide estimator for mean annual flood which would be superior to the set of equations for the regions in Beable and McKerchar and the contour maps in McKerchar and Pearson. This hope arose because highly permeable basins such as those in the central North Island, which had the highest values for hydrogeology, drainage and the permeability parameters, have low values of $Q_m/A^{0.8}$, whereas other basins where infiltration rates were low (e.g. sites 46662, 46663, both in Northland) had low values for hydrogeology, drainage and permeability and quite high values of $Q_m/A^{0.8}$.

The results achieved are negative: it could not be demonstrated that basin data inferred from Land Resource Inventory (slope, hydrogeology, soil drainage, soil porosity) were useful in improving estimators for mean annual flood. This null result is a disappointment because it closes off what was perceived to be a promising line of investigation. Even though some extreme basins (e.g. Maryburn) seemed to have basin parameters which qualitatively explained their flood statistics, the variability of basin properties and particularly basin annual flood series is too large to obtain predictive equations.

After area, storm rainfall intensity, quantified by the five-year return period 24-hour duration rainfall from Tomlinson's (1979) maps, clearly remains the most important variable, but for small basins where critical storm duration is much less than 24 hours, this statistic is limited. The 1-hour storm rainfall statistic, based on a much smaller sample of records from automatic raingauges, is apparently less accurate and less useful.

RECOMMENDATIONS AND CONCLUSIONS

Parameters which characterise the hydrogeology, slope and infiltration properties of basins can be obtained from the NZ Land Resource Inventory.

The analysis undertaken could not devise predictors using these parameters for mean annual flood for small basins that were improvements over the contoured maps in McKerchar and Pearson.

Two further lines of enquiry will be investigated for small basin mean annual flood estimation in future:

- 1. Continued statistical approach with basin geometry and geomorphological variables used in the multiplicative regressions.
- More deterministic approaches using physically-based rainfall-runoff models in conjunction with small-scale thunderstorm rainfalls.

In the meantime, the McKerchar and Pearson contour maps are recommended for estimating mean annual flood. Examples of robust regional flood frequency procedures for small basins are given in Pearson (this volume).
